

Control of a Chemical Plant

Helin Geleri

Serkan Basaran

System Overview

System Configuration: The plant consists of three main interconnected unit operations: two chemical reactors arranged in series followed by a final separator.

In the analysis we considered the model of the system **linearized around the equilibrium position**.

Control Objective: The primary goal is to manage the output levels of reactors and separator and product weight percent X_{B3} by adjusting fresh feed flows F_{f1} , F_{f2} recycle flow F_R and heat inputs Q_1, Q_2, Q_3

$$y = [H_1 \quad x_{A1} \quad x_{B1} \quad T_1 \quad H_2 \quad x_{A2} \quad x_{B2} \quad T_2 \quad H_3 \quad x_{A3} \quad x_{B3} \quad T_3]$$

$$u = [F_{f1} \quad Q_1 \quad F_{f2} \quad Q_2 \quad F_R \quad Q_3].$$

Steady States Values

Steady states and parameters.

Parameter	Value	Units
H_1	29.8	m
x_{A1}	0.542	wt(%)
x_{B1}	0.393	wt(%)
T_1	315	K
H_2	30	m
x_{A2}	0.503	wt(%)
x_{B2}	0.421	wt(%)
T_2	315	K
H_3	3.27	m
x_{A3}	0.238	wt(%)
x_{B3}	0.570	wt(%)
T_3	315	K

Input constraints.

Parameter	Lower bound	Steady state	Upper bound	Units
F_{f1}	0	8.33	10	kg/s
Q_1	0	10	50	kJ/s
F_{f2}	0	0.5	10	kg/s
Q_2	0	10	50	kJ/s
F_R	0	66.2	75	kg/s
Q_3	0	10	50	kJ/s

Matrix Decomposition

Modeling: The plant is modeled as a large-scale system that can be partitioned into three independent subsystems (Reactor 1, Reactor 2, and the Separator) for distributed control analysis.

$$\begin{array}{lll} y_1 = [H_1 & x_{A1} & x_{B1} \quad T_1] & u_1 = [F_{f1} \quad Q_1] & \textbf{Reactor 1} \\ y_2 = [H_2 & x_{A2} & x_{B2} \quad T_2] & u_2 = [F_{f2} \quad Q_2] & \textbf{Reactor 2} \\ y_3 = [H_3 & x_{A3} & x_{B3} \quad T_3] & u_3 = [F_R \quad Q_3] & \textbf{Seperator} \end{array}$$

CONCLUSIONS

- **Dynamic Response and Trade-offs:** While the settling times for levels H_1 , H_2 and H_3 slowed by approximately 0.7–1 second compared to the open-loop response, this sacrifice in speed enabled a significant 5-second gain in the control of the critical product quality variable, X_{B3}
- **Constraint Satisfaction:** All strict input constraints were successfully maintained without violation, with specific emphasis on the feed flow F_{f2} ensuring the process remained within safe physical and operational limits at all times.
- **Distributed Topology Preference:** Due to the coupled dynamics inherent in the reactor-separator sequence, a String Distributed control structure is preferred as it preserves the flexibility of independent unit operations while managing plantwide interactions.

$T_s = 4.00\text{s}$ | $OS_{ss} = 0.039\%$

- Much harder to impose min. decay. rate in decentralised.
- $\|K\| = 1486$, more aggressive even for a more relaxed condition.

Decentralized Structure
Spectral Radius (ρ) = 0.8474

DT - DECENTR - INPUT ELLIPSE - $\text{RHO} = 0.85$ – (pg.2)

Decentralized | DT Flow Deviations (ZOH)

Decentralized | DT Heat Deviations (ZOH)

- More aggressive inputs observed.

DT - STRING - INPUT ELLIPSE - $\text{RHO} = 0.80$ – (pg.1)

String - Discrete-Time Performance Analysis

- Can achieve the centralized case's min. decay rate.
- $\|K\| = 580$, less aggressive than decentralised.

DT - STRING - INPUT ELLIPSE - $\text{RHO} = 0.80$ – (pg.2)

String | DT Flow Deviations (ZOH)

String | DT Heat Deviations (ZOH)

- Similar to the centralized case again.
- Additionally, can't force tighter disk constraints in the string topology, unlike in the centralized case.

H2-NORM MINIMIZATION WITH LMIs

$$\begin{aligned}x_{k+1} &= Fx_k + Gu_k + G_w w_k \\z_k &= Hx_k + D_u u_k\end{aligned}$$

Choosing LQ-like performance: $H = \begin{bmatrix} \sqrt{Q} \\ 0 \end{bmatrix}, D_u = \begin{bmatrix} 0 \\ \sqrt{R} \end{bmatrix}$

$$\min_{Y, S, L} \text{trace}(S)$$

$$L = K_x P$$

s. t.

$$\begin{bmatrix} P - FPF^T - FL^T G^T - GLF^T - G_w G_w^T & GL \\ L^T G^T & P \end{bmatrix} \geq 0$$

$$\begin{bmatrix} S & HP + D_u L \\ L^T D_u^T + PH^T & P \end{bmatrix} \geq 0$$

Partitioned weight matrices:

$$Q_{y_1} = \text{diag}(1, 0, 0, 0.1)$$

$$Q_{y_2} = \text{diag}(1, 0, 0, 0.1)$$

$$Q_{y_3} = \text{diag}(1, 0, 10^3, 0)$$

$$R_1 = R_2 = R_3 = 0.01I$$

DT - CENTR - INPUT ELLIPSE - H2 MINIMIZATION – (pg.1)

Centralized - Discrete-Time Performance Analysis

- Faster settling times on all inspected states compared to open loop.
- $\|K\| = 5.26$

DT - CENTR - INPUT ELLIPSE - H2 MINIMIZATION – (pg.2)

Centralized | DT Flow Deviations (ZOH)

Centralized | DT Heat Deviations (ZOH)

DT - DECENTR - INPUT ELLIPSE - H2 MINIMIZATION – (pg.1)

Decentralized - Discrete-Time Performance Analysis

H1 (Reactor 1 Level)
 $T_s = 1.20s \mid OS_{ss} = 0.000\%$

H2 (Reactor 2 Level)
 $T_s = 1.50s \mid OS_{ss} = 0.000\%$

H3 (Separator Level)
 $T_s = 1.30s \mid OS_{ss} = 0.000\%$

XB3 (Product Concentration)
 $T_s = 7.50s \mid OS_{ss} = 0.043\%$

- Theoretically still controllable, but problem becomes “ill-conditioned”.
- $\|K\| = 3.79$
- Worse settling times.

Decentralized Structure
Spectral Radius (ρ) = 0.9252

DT - DECENTR - INPUT ELLIPSE - H2 MINIMIZATION – (pg.2)

Decentralized | DT Flow Deviations (ZOH)

Decentralized | DT Heat Deviations (ZOH)

DT - STRING - INPUT ELLIPSE - H2 MINIMIZATION

String - Discrete-Time Performance Analysis

- Still ill-conditioned like the decentralized case.
- $\|K\| = 4.32$
- Worse settling times than the centralized case.

- Centralized gain matrix K below shows heavier info-exchange back and forth between reactor 1 - reactor 2 that can't be captured by the decentralized / string.

H2 (Reactor 2 Level)
 $T_s = 0.80s$ | $OS_{ss} = 0.000\%$

H3 (Separator Level)
 $T_s = 0.90s$ | $OS_{ss} = 0.000\%$

XB3 (Product Concentration)
 $T_s = 6.60s$ | $OS_{ss} = 0.044\%$

String | DT Flow Deviations (ZOH)

F_{f1} (Feed Flow 1)

F_{f2} (Feed Flow 2)

F_R (Recycle Flow)

Ff2 critically approaches the lower bound.

- When we drop the input constraints and employ H2 minimization alone with the same parameters, we get a “feasible” solution.
- $\|K\| = 4.97$
- Still worse settling times than the centralized case, but offers improvement in state trajectories over the decentralized case.

CONCLUSION

- Like in the C.T. case, it's difficult to observe direct consequences of a global constraint on a single comparison metric or on a few states of interest.
- xB3 offers the main window of improvement via control strategies. For the centralised case, the shifted disk constraint provides a good trade-off, reducing xB3 settling time without introducing overshoots in reactor levels.
- Decentralized cases significantly tighten the achievable performance constraints. This is mainly due to strong coupling: direct flow between adjacent tanks and feedback flow from the last tank to the first.
- The string topology introduces a significant improvement over the decentralized case, as expected, and enables feasibility under different control criteria.
- H₂ control allows fast settling without overshoot in levels; however, it provides limited improvement in xB3 product concentration dynamics.
